Beach — Answer Key

Did you know?

- Sand is typically made of tiny fragments of rock, shell and coral, worn down over long periods by waves and weather.
- Some beaches have unusually colored sand, like black volcanic sand or pink sand mixed with crushed coral and shell.
- Tides, caused mainly by the Moon's gravitational pull, change how much beach is exposed throughout the day.
- Riptides are strong, narrow currents that can pull swimmers away from shore, distinct from the regular in-and-out motion of waves.
